Abstract
The subject of this paper is a program verification method that takes into account abortion caused by partial functions in program statements. In particular, boolean expressions of various statements will be investigated that are not well-defined. For example, a loop aborts if its execution begins in a state for which the loop condition is undefined. This work considers the program constructs of nondeterministic sequential programs and also deals with the synchronization statement of parallel programs introduced by Owicki and Gries [Owi76]. The syntax of program constructs will be reviewed and their semantics will be formally defined in such a way that they suit the relational model of programming developed at Eötvös Loránd University [Fot88, Fot95]. This relational model defines the program as a set of its possible executions and also provides definition for other important programming notions, like problem and solution. The proof rules of total correctness [Dij76, Fot05, Gri81, Hoa69, Owi76] will be extended by treating abortion caused by partial functions. The use of these rules will be demonstrated by means of a verification case study.

1 Introduction
In mathematics, a partial function is a binary relation from \( X \) to \( Y \) that does not map every element of \( X \) to an element of \( Y \). It is well-known that the expression \( a/b \) is not defined if the divisor \( b \) is zero. But even the subtraction \( x - y \) may have no defined value, it occurs if \( x \) and \( y \) are natural numbers and \( x \) is less than \( y \), and the expected value also should be a natural number. More precisely, \( f : \mathbb{N} \times \mathbb{N} \to \mathbb{N} \) (where \( f(x - y) = x - y \)) is a partial function, because not every element of the set \( \mathbb{N} \times \mathbb{N} \) is in the domain of \( f \). The value of a partial function is undefined when its argument is out of the domain of the partial function.

In programming, an attempt to divide by zero is handled in various ways depending on the programming environment. It either leads to a compile-time error or produces catchable runtime error if it happens at runtime. In general, evaluation to an undefined value may lead to exception or undefined behaviour. Programmers encounter with expressions on a daily basis, when they are constructing statements. The most commonly used form of the assignment statement sets the value of an expression to a variable. Particularly, boolean expressions are concerned when one writes loop condition or conditions of an alternative command. The value of these expressions is not certainly defined mathematically.

There are programs that have to work without any error. To be able to reason about the correctness of such programs we need to have a rigorous definition of the semantics of the language of these programs. We also need methods that allow us to verify the correctness of programs. When one provides the semantics of a program construct, the functions that are used to build the programming statement (loop condition for example) are assumed to be total functions. The verification methods also consider program descriptions where these functions are well-defined.

This paper focuses on partial functions in program descriptions. In particular, not well defined boolean expressions of various statements will be considered. They will be taken into account when providing the semantics of statements. The semantics of program constructs are given in such a way that they suit an existing relational programming model. This model defines the basic concepts of programming, for example defines the program as a set of its possible executions. A verification method will be presented as well, that handles statements containing partial logical functions. Some rules of the verification method are well known, the new rules will be given along with their proof.

The rest of this paper is organized as follows. Section 2 reviews how partial functions are handled in the literature. Section 3 introduces keywords that are allowed to use to build programs we want to investigate. Next, the semantics of these elementary programs and construct are provided. The mentioned relational programming model is also presented here shortly. Then we provide verification rule for each statement that can be formed from our keywords. Section 4 presents a verification example and illustrates the use of the verification rules given in the previous section. Section 5 summarizes our approach and work.

Definition 2. Let $A$ be a state space and $\sigma \in A$ be the current state.

$\text{skip}(\sigma) := \{< \sigma >\}$
Definition 3. Let $A$ be a state space and $\sigma \in A$ be the current state.

$\text{abort}(\sigma) := \{<\sigma, \text{fail}>\}$

Definition 4. Let $A$ be a state space and $f \subseteq A \times A$ be a relation and $\sigma \in A$ be the current state.

$(\psi := f(\psi))(\sigma) := \{<\sigma, \sigma'> | \sigma' \in f(\sigma)\} \quad \text{if} \, \sigma \in D_f$

$\{<\sigma, \text{fail}>\} \quad \text{if} \, \sigma \notin D_f$

Definition 5. Let $A$ be the common base state space of the program $S_1$ and $S_2$. Let $\sigma \in A$ be the current state.

$(S_1; S_2)(\sigma) := \{\alpha | \alpha \in S_1(\sigma) \cap \overline{A}^\infty \} \cup \{\alpha | \alpha \in S_1(\sigma) \land \alpha \sim <\infty \land \alpha_{[\alpha]} = \text{fail}\} \cup \{\alpha \otimes \beta | \alpha \in S_1(\sigma) \cap \overline{A}^\infty \land \beta \in S_2(\alpha_{[\alpha]})\}$

Definition 6. Let $A$ be the common base state space of the program $S_1 \ldots S_n$ and the conditions $\pi_1 \ldots \pi_n$. Let $\sigma \in A$ be the current state.

$(\text{if } \pi_1 \rightarrow S_1 \cdots \pi_n \rightarrow S_n \text{ fi})(\sigma) := \omega(\sigma) \cup \bigcup_{i=1}^n S_i(\sigma)$

where $\omega(\sigma) = \{<\sigma, \text{fail}>\} \quad \text{if} \, \exists i \in [1..n] : \sigma \notin D_{\pi_i} \lor \forall i \in [1..n] : \sigma \notin D_{\pi_i} \land \neg \pi_i(\sigma)$

$\emptyset \quad \text{otherwise}$

Definition 7. Let $A$ be the common base state space of the program $S_0$ and the condition $\pi$. Let $\sigma \in A$ be the current state.

$(\text{while } \pi \text{ do } S_0 \text{ od})(\sigma) := \begin{cases} (S_0; \text{while } \pi \text{ do } S_0 \text{ od})(\sigma) & \text{if} \, \sigma \in D_\pi \land \pi(\sigma) \\ \{<\sigma>\} & \text{if} \, \sigma \in D_\pi \land \neg \pi(\sigma) \\ \{<\sigma, \text{fail}>\} & \text{if} \, \sigma \notin D_\pi \end{cases}$

Definition 8. Let $A$ be a state space and $f \subseteq A \times A$ be a relation and $\sigma \in A$ be the current state.

$[S](\sigma) := S(\sigma)$

Definition 9. Let $A$ be the common base state space of the program $S_0$ and the condition $\beta$. Let $\sigma \in A$ be the current state.

$(\text{await } \beta \text{ then } S_0 \text{ ta})(\sigma) := \begin{cases} [S_0](\sigma) & \text{if} \, \sigma \in D_\beta \land \beta(\sigma) \\ \{<\sigma, \text{fail}>\} & \text{if} \, \sigma \notin D_\beta \end{cases}$

Before the definition of the parallel composition the concept of the “uninterrupted” must be introduced. Let $S$ be a program and $\sigma$ be an arbitrary state of its base state space. The execution $S(\sigma)$ is uninterrupted if the program $S$ is the skip, abort, an assignment statement, an atomic region $[P]$ or an await statement $\text{await } \beta \text{ then } S_0 \text{ ta}$ where $\sigma \notin D_\beta$ or $\beta(\sigma)$ is true. (In these cases the await statement is the abort or the atomic region $[S_0]$.)

We must remark that in case of $S(\sigma)$ is not uninterrupted (where $\sigma$ is an arbitrary state and $S$ is a program), then $S$ can be always splitted into two programs so that $S(\sigma) = (u:T)(\sigma)$ so that $u(\sigma)$ is uninterrupted. This $u$ is named as the first statement of $S$ and $T$ is the remainder part of $S$ relative to the state $\sigma$.

• If $S = \text{await } \beta \text{ then } S_0 \text{ ta}$ and $\sigma \in D_\beta \land \neg \beta(\sigma)$, then $u$ is skip and $T$ is $\text{await } \beta \text{ then } S_0 \text{ ta}$.

• If $S = (S_1; S_2)$ and $S_1(\sigma)$ is uninterrupted, then the $u$ is $S_1$ and $T$ is $S_2$.

• If $S = (S_1; S_2)$ and $S_1(\sigma)$ is not uninterrupted, then $u$ is the first statement of $S_1$ and $T$ is the sequence $(T_1; S_2)$ where $T_1$ is the remainder part of $S_1$.
• If $S = \text{if } \pi_1 \rightarrow S_1 \sqcup \ldots \sqcup \pi_n \rightarrow S_n \text{ fi}$ and one of its conditions is not defined or all conditions are false in $\sigma$ ($\exists i \in [1..n]: \sigma \notin D_{\pi_i} \lor \forall i \in [1..n]: \sigma \in D_{\pi_i} \land \neg \pi_i(\sigma)$), then $u$ is abort and $T$ is abort.

• If $S = \text{if } \pi_1 \rightarrow S_1 \sqcup \ldots \sqcup \pi_n \rightarrow S_n \text{ fi}$ and all conditions are defined and some of them are true in $\sigma$ ($\forall i \in [1..n]: \sigma \in D_{\pi_i} \land \exists i \in [1..n]: \pi_i(\sigma)$), then $u$ is skip and $T$ is $S_i$ assuming the $i^{th}$ branch is selected by the scheduler.

• If $S = \text{while } \pi \text{ do } S_0 \text{ od}$ and its condition is not defined ($\pi \notin D_{\pi}$), then $u$ is abort and $T$ is abort.

• If $S = \text{while } \pi \text{ do } S_0 \text{ od}$ and the condition is false in $\sigma$ ($\sigma \in D_{\pi} \land \neg \pi(\sigma)$), then $u$ is skip and the reminder part of $S$ is skip.

• If $S = \text{while } \pi \text{ do } S_0 \text{ od}$ and the condition is true in $\sigma$ ($\sigma \in D_{\pi} \land \pi(\sigma)$), then $u$ is skip and $T$ is $(S_0; \text{while } \pi \text{ do } S_0 \text{ od})$.

• If $S = \text{parbegin } P_1 \parallel \cdots \parallel P_i \parallel \cdots \parallel P_n \text{ parend}$ and its $i^{th}$ branch is selected by the scheduler and $P_i(\sigma)$ is uninterrupted, then $u$ is $P_i$ and $T$ is $\text{parbegin } P_1 \parallel \cdots \parallel P_{i-1} \parallel P_{i+1} \parallel \cdots \parallel P_n \text{ parend}$.

• If $S = \text{parbegin } P_1 \parallel \cdots \parallel P_i \parallel \cdots \parallel P_n \text{ parend}$ and its $i^{th}$ branch is selected by the scheduler and $P_i(\sigma)$ is not uninterrupted, then $u$ is the first statement of $P_i$ and $T$ is $\text{parbegin } P_1 \parallel \cdots \parallel T_i \parallel \cdots \parallel P_n \text{ parend}$ where $T_i$ is the reminder part of $P_i$.

Definition 10. Let $A$ be the common base state space of the programs $S_1, \ldots, S_n$ and $\sigma \in A$ be the current state.

$\text{(parbegin } S_1 \parallel \cdots \parallel S_i \parallel \cdots \parallel S_n \text{ parend})(\sigma) := \bigcup_{i=1}^{n} B_i(\sigma)$

where

$B_i(\sigma) = \begin{cases} (S_i; \text{parbegin } S_1 \parallel \cdots \parallel S_{i-1} \parallel S_{i+1} \parallel \cdots \parallel S_n \text{ parend})(\sigma) & \text{if } S_i(\sigma) \text{ is uninterrupted} \\ (u_i; \text{parbegin } S_1 \parallel \cdots \parallel S_{i-1} \parallel T_i \parallel S_{i+1} \parallel \cdots \parallel S_n \text{ parend})(\sigma) & \text{if } S_i(\sigma) = (u_i; T_i)(\sigma) \text{ where } u_i(\sigma) \text{ is uninterrupted} \end{cases}$

3.3 Verification

Informally, a program is correct if it satisfies the intended input/output relation. Program correctness is expressed by so-called correctness formulas. These are statements of the form

$\{Q\} S \{R\}$

where $S$ is a program and $Q$ and $R$ are assertions. The assertion $Q$ is the precondition of the correctness formula and $R$ is the postcondition. The precondition describes the set of initial states in which the program $S$ is started and the postcondition describes the set of desirable final states.

More precisely: a correctness formula is true if every execution of $S$ that starts in a state satisfying $Q$ is finite (it terminates) and its final state satisfies $R$. (This is the concept of the total correctness. The partial correctness is omitted in this paper.)

Reasoning about correctness formulas in terms of semantics is not very convenient. Hoare has introduced a proof system allowing us to prove partial correctness of deterministic programs in a syntax-directed manner, by induction on the program syntax [Hoa69]. Dijkstra, Gries and Owicki have developed this system for nondeterministic and parallel programs [Di76, Gri81, Owi76]. Now this system is going to be extended.

The first six rules are well-known, they are only shown for the sake of completeness without their proofs.

Theorem 1. Let $Q$ and $R$ be two assertions.

$Q \implies R$

$\{Q\} \text{ skip } \{R\}$

Theorem 2. Let $Q$ and $R$ be two assertions, $v := f(\nu)$ be an assignment.

$Q \implies v \in D_T \land \forall \nu \in f(\nu) : R^{\nu \leftrightarrow \nu}$

$\{Q\} v := f(\nu) \{R\}$
The $R^{f:Z}$ means that the components of $\pi$ must be substituted for the corresponding components of $v$. In that case when the relation $f \subseteq A \times A$ of the assignment is a total function, i.e., $f$ is a (deterministic) function mapping from $A$ to $A$ and $D_f = A$, the rule of assignment can be written in the following form.

$$Q \implies R^{f:Z}_{(v)}$$

$\{\{Q\}\} v := f(v) \{\{R\}\}$

**Theorem 3.** Let $Q$ and $R$ be two assertions, $S$ be a program.

$$\{\{Q\}\} S \{\{R\}\}$$

**Theorem 4.** Let $Q$ and $R$ be two assertions, $S_1$ and $S_2$ be two programs.

$$\exists Q' : A \rightarrow L$$

$$\{\{Q\}\} S_1 \{\{Q'\}\}$$

$$\{\{Q'\}\} S_2 \{\{R\}\}$$

$$\{\{Q\}\} (S_1; S_2) \{\{R\}\}$$

**Theorem 5.** Let $Q$ and $R$ be two assertions, and $S^*$ stand for the program $S$ annotated with assertions such as preconditions of the assignments or invariants of the loops.

$$\{\{Q\}\} S^* \{\{R\}\}$$

$$\{\{Q\}\} S \{\{R\}\}$$

The next three rules take into consideration the cases when some logical functions of the construction is not well-defined. These rules are the extensions of the well-known versions that use well-defined logical functions. An assertion $P$ will be interpreted as the set of states that satisfy $P$ many times in the following rules. From its context it can be decided which interpretation holds. For example, $Q$ and $R$ are assertions in the expression $Q \implies R$ but they are sets in $Q \subseteq R$.

**Theorem 6.** Let $Q$ and $R$ be two assertions, and $S_1, \ldots, S_n$ be programs and $\pi_1, \ldots, \pi_n$ be conditions.

$$Q \implies \pi_1 \land \cdots \land \pi_n$$

$$Q \subseteq D_{\pi_1} \cap \cdots \cap D_{\pi_n}$$

$$\forall i \in \{1, \ldots, n\} : \{\{Q \land \pi_i\}\} S_i \{\{R\}\}$$

$$\{\{Q\}\} \text{if } \pi_1 \rightarrow S_1 \circ \cdots \circ \pi_n \rightarrow S_n \text{ fi } \{\{R\}\}$$

Proof. We must show that the executions of the conditional statement starting from $Q$ finish at $R$. Let $q$ be an arbitrary state of $Q$. Since $Q \subseteq D_{\pi_1} \cap \cdots \cap D_{\pi_n}$ and $Q \implies \pi_1 \land \cdots \land \pi_n$, according to the definition each execution of the conditional statement starting from $q$ belongs to the executions of the component $S_i$ where its condition $\pi_i$ is satisfied by $q$.

These executions terminate in a state satisfying $R$ because $\forall i \in \{1, \ldots, n\} : \{\{Q \land \pi_i\}\} S_i \{\{R\}\}$ thus $\{\{Q\}\} \text{ if } \pi_1 \rightarrow S_1 \circ \cdots \circ \pi_n \rightarrow S_n \text{ fi } \{\{R\}\}$ holds.

**Theorem 7.** Let $Q$ and $R$ be two assertions, and $S_0$ be a program and $\pi$ be a condition.

$$\exists I : A \rightarrow L \text{ and } \exists t : A \rightarrow Z$$

$$Q \implies I$$

$$I \subseteq D_\pi$$

$$I \land \neg \pi \implies R$$

$$I \land \pi \implies t \geq 0$$

$$\{\{I \land \pi\}\} S_0 \{\{I\}\}$$

$$\forall c_0 \in Z : \{\{I \land \pi \land t = c_0\}\} S_0 \{\{t < c_0\}\}$$

$$\{\{Q\}\} \text{ while } \pi \text{ do } S_0 \text{ od } \{\{R\}\}$$
Proof. We need to prove that the executions of the loop starting from \( q \) are finite and they finish at \( R \). Let \( q \) be an arbitrary state of \( Q \). Since \( Q \Rightarrow I \) and \( I \subseteq D_\pi \) thus \( q \in D_\pi \).

The execution starting from \( q \) can be split into the sections of the executions generated by the body \( S_0 \). Each section is started at a state satisfying \( I \land \pi \) and terminates at a state satisfying \( I \) (see the cond. \( \{ I \land \pi \}\} S_0 \{ I \}) \). If the total execution is finite, its last section finishes at a state satisfying \( \neg \pi \) or the state \( q \) own satisfies \( \neg \pi \) if the loop stops at once. It means that each finite execution starting from \( q \) finishes at a state of \( R \) since \( I \land \neg \pi \Rightarrow R \).

The proof will be complete if we show that there is no infinite execution from \( q \). If there would be an infinite execution, it should consist of infinite sections. Let us consider the infinite sequence of integers that is mapped from the beginning states of the sections by the function \( t \). Because of the criterion \( \forall c_0 \in \mathbb{Z} : \{ \{ I \land \pi \land t = c_0 \}\} S_0 \{ \{ t < c_0 \}\} \) this sequence should be strictly monotone decreasing thus it should contain negative numbers. However all numbers must be nonnegative because of the criterion \( I \land \pi \Rightarrow t \geq 0 \). This is a contradiction. \( \square \)

**Theorem 8.** Let \( Q \) and \( R \) be two assertions, and \( S_0 \) be a program and \( \beta \) be a condition.

\[
\begin{align*}
Q \subseteq D_\beta \\
\{(Q \land \beta)\} S_0 \{(R)\} \\
\{\{Q\}\} \text{ await } \beta \text{ then } S_0 \text{ ta } \{(R)\}
\end{align*}
\]

Proof. It is enough to show that the executions of the conditional statement starting from \( Q \) finish at \( R \). Let \( q \) be an arbitrary state of \( Q \). If \( q \in D_\beta \) and \( q \) satisfies \( \beta \), the executions of the await-statement starting from \( q \) are identical to the executions of the atomic region \( S_0 \) starting from \( q \). These executions finish at a state in \( R \) because of \( \{(Q \land \beta)\} S_0 \{(R)\} \).

The last rule is about the parallel composition.

**Theorem 9.** Let \( Q, Q_1, \ldots, Q_n \) and \( R, R_1, \ldots, R_n \) be assertions, \( S_1, \ldots, S_n \) be programs, and \( S_1^*, \ldots, S_n^* \) be the annotations of the corresponded programs.

\[
\begin{align*}
Q \Rightarrow Q_1 \land \ldots \land Q_n \\
\forall i \in \{1, \ldots, n\} : \{(Q_i)\} S_i^* \{(R_i)\}
\end{align*}
\]

and they are interference free

\[
R_1 \land \ldots \land R_n \Rightarrow R
\]

\[
\{\{Q\}\} \text{ parbegin } S_1 \parallel \cdots \parallel S_n \text{ parend } \{(R)\}
\]

where standard proof outlines \( \{(Q_i)\} S_i^* \{(R_i)\} \), \( i \in \{1, \ldots, n\} \), are called interference free if no normal assignment or atomic region \( u \) of a component program \( S_i \) interferes with the proof outline \( \{(Q_i)\} S_i^* \{(R_i)\} \) of another component program \( S_j \) where \( i \neq j \). We say that \( u \) does not interfere with \( \{(Q)\} S^* \{(R)\} \) if the following conditions are satisfied:

1. for all assertions \( r \) in \( \{(Q)\} S^* \{(R)\} \) the formula \( \{ r \land \text{pre}(u) \} u \{ \{ r \} \} \) holds, where \( \text{pre}(u) \) is the precondition of \( u \) in the annotation \( S^* \),

2. for all termination function \( t : \bar{A} \rightarrow \mathbb{Z} \) in \( \{(Q)\} S^* \{(R)\} \) where \( A \) is the base state space of the parallel composition the formula \( \{ \text{pre}(u) \land t = c_0 \} u \{ \{ t \leq c_0 \} \} \) holds, where \( c_0 \) is an arbitrary integer.

### 4 Case Study

Consider the following problem: given an array \( x \) of \( n \) integer numbers and an integer number \( k \). Count the elements of \( x \) that are divisors of \( k \).

Specification of the problem can be given in the following way:

\[
A = (x : \mathbb{Z}^n, k : \mathbb{Z}, \text{count} : \mathbb{N})
\]

\[
\text{Pre} = (x = x')
\]

\[
\text{Post} = (\text{Pre} \land \text{count} = \sum_{j=1}^{n} \chi(x[j] | k))
\]

where \( \chi : \mathbb{L} \rightarrow \{0, 1\} \) and \( \chi(\text{true}) = 1 \) and \( \chi(\text{false}) = 0 \)

Let \( S \) denote the following program:
i, count := 1, 0
while i ≤ n do
    if
        x[i] ∣ k → count := count + 1 □
        x[i] ∤ k → skip
    fi;
    i := i + 1
od

Let $Q'$ denote the intermediate assertion of the sequence $S$, between the initialisation and the loop, $Q''$ the intermediate assertion that holds before executing the assignment $i := i + 1$, $Inv$ the invariant and $t$ the variant function of the loop.

Now we shall prove that $\{ \{ Pre \} \} S \{ \{ Post \} \}$ holds. Since $S$ is a sequence, due to Theorem 4. it is sufficient to prove that

1. $\{ \{ Pre \} \} i, count := 1, 0 \{ \{ Q' \} \}$ and
2. $\{ \{ Q' \} \} DO \{ \{ Post \} \}$, where $DO$ denotes the loop:
   while $i \leq n$ do if $x[i] \mid k \rightarrow count := count + 1$ □ $x[i] \nmid k \rightarrow skip$ fi; $i := i + 1$ od
   and $Q' = (Pre \land count = 0 \land i = 1)$ is given.

Let us prove the two conditions:

1. $\{ \{ Pre \} \} i, count := 1, 0 \{ \{ Q' \} \}$

   By replacing $i$ with 1 and $count$ with 0 in $Q'$ we obtain $(Pre \land 0 = 0 \land 1 = 1)$, that is $Pre$. Obviously $Pre \Longrightarrow Pre$ holds. We proved that $Pre \Longrightarrow Q'_{i=1, count=0}$ holds. Now, by the remark of Theorem 2. $\{ \{ Pre \} \} i, count := 1, 0 \{ \{ Q' \} \}$ is deduced.

2. $\{ \{ Q' \} \} DO \{ \{ Post \} \}$

   Instead of proving this verification condition, due to Theorem 7. it is sufficient to prove that
   
   (a) $Q' \Longrightarrow Inv$ and
   (b) $Inv \subseteq D_{i \leq n}$ and
   (c) $Inv \land \neg (i \leq n) \Longrightarrow Post$ and
   (d) $Inv \land i \leq n \Longrightarrow n - i \geq 0$ and
   (e) $\forall c_0 \in Z: \{ \{ Inv \land i \leq n \land n - i = c_0 \} \}$ $S_0 \{ \{ Inv \land n - i < c_0 \} \}$
   
   where $S_0$ denotes the loop body if $x[i] \mid k \rightarrow count := count + 1$ □ $x[i] \nmid k \rightarrow skip$ fi; $i := i + 1$. and the loop invariant $Inv$ and the variant function $t$ are given as follows:

   $Inv = (Pre \land i \in [1..n+1] \land count = \sum_{j=1}^{i-1} \chi(x[j] \mid k))$

   $t = n - i$

   Let us prove the conditions separately:

   (a) $Q' \Longrightarrow Inv$

   We have to prove that $Q'$ implies
   
   i. $Pre$

   This holds since $Q'$ contains $Pre$.

   ii. $i \in [1..n+1]$

   Since $i = 1$, $i$ is an element of the not empty set $[1..n+1]$. The interval $[1..n+1]$ is not empty, because $n$, that is the length of the array $x$, is zero or a positive integer number.

   iii. $count = \sum_{j=1}^{i-1} \chi(x[j] \mid k)$

   Due to condition $Q'$, $count = 0$ and $i = 1$. Thus the sum is empty and its value is also 0.
(b) \( \text{Inv} \subseteq \mathcal{D}_{\leq n} \)

Since \( i \leq n \) is a well-defined logical function, its domain contains all states of the statespace, including those that satisfy \( \text{Inv} \).

(c) \( \text{Inv} \wedge \neg(i \leq n) \implies \text{Post} \)

i. \( \text{Pre} \)

The invariant contains the precondition, therefore \( \text{Inv} \) implies \( \text{Pre} \).

ii. \( \text{count} = \sum_{j=1}^{n} \chi(x[j] \mid k) \)

Since \( i \in [1..n+1] \) and \( \neg(i \leq n) \), therefore we get \( i = n + 1 \).

This, together with \( \text{count} = \sum_{j=1}^{i-1} \chi(j \mid k) \) we know from \( \text{Inv} \), yields the desired condition.

(d) \( \text{Inv} \wedge i \leq n \implies n - i \geq 0 \)

This holds because due to the loop condition \( i \leq n \) is true.

(e) \( \forall c_0 \in \mathbb{Z}: \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0\}\} S_0 \{\{\text{Inv} \wedge n-i < c_0\}\} \)

Let \( c_0 \) be an arbitrary integer number. Since the loop body \( S_0 \) is a sequence, we use Theorem 4. with \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \) as \( Q \) and with \( \text{Inv} \wedge n-i < c_0 \) as \( R \). It is sufficient to prove the following two conditions:

i. \( \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0\}\} \text{IF} \{\{Q''\}\} \) and

ii. \( \{\{Q''\}\} i := i + 1 \{\{P \wedge n-i < c_0\}\} \)

where \( \text{IF} \) denotes the conditional statement if \( x[i] \mid k \rightarrow \text{count} := \text{count} + 1 \square x[i] \mid k \rightarrow \text{skip} \text{ fi} \) and the intermediate assertion of the loop body is \( Q'' \) is given: \( Q'' = \text{Inv}^{i+1} \wedge n-i = c_0 \)

i. \( \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0\}\} \text{IF} \{\{Q''\}\} \)

Due to Theorem 6., the following conditions are sufficient to prove:

A. \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \implies (x[i] \mid k \lor x[i] \mid k) \) and

B. \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \subseteq D_{x[i] \mid k} \cap D_{x[i] \mid k} \)

C. \( \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0 \wedge x[i] \mid k \wedge n-i = c_0\}\} \text{count} := \text{count} + 1 \{\{Q''\}\} \) and

D. \( \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0 \wedge x[i] \mid k \wedge n-i = c_0\}\} \text{skip} \{\{Q''\}\} \)

Let us prove the conditions separately:

A. \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \implies (x[i] \mid k \lor x[i] \mid k) \)

For each state of the statespace for which \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \) holds, either \( x[i] \) is a divisor of \( k \) or \( x[i] \) is not a divisor of \( k \).

B. \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \subseteq D_{x[i] \mid k} \cap D_{x[i] \mid k} \)

In order to ensure that \( x[i] \mid k \) and \( x[i] \mid k \) are well-defined functions, we have to take into account not only that the divisibility \( x[i] \mid k \) can be answered only if \( x[i] \) is not zero, but the index \( i \) has to be inside the bounds of the array \( x \). More precisely, we want to prove that \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \implies i \in [1..n] \wedge x[i] \neq 0 \wedge i \in [1..n] \wedge x[i] \neq 0 \).

Although \( i \in [1..n+1] \) (due to the invariant) and the loop condition \( i \leq n \) together allow us to deduce that \( i \in [1..n] \) holds, we cannot guarantee that each state of the statespace for which \( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \) holds, \( x[i] \) is not 0. The reason is, that there is no assumption for the elements of \( x \), except that they are integer numbers. The case when \( x[i] = 0 \), is not excluded by any condition we know and are allowed to use. If \( x[i] \) equals 0, the expressions \( x[i] \mid k \) and \( x[i] \mid k \) have no defined value. The current condition cannot be proven. We provide the remaining part of the proof for the sake of completeness.

C. \( \{\{\text{Inv} \wedge i \leq n \wedge n-i = c_0 \wedge x[i] \mid k \wedge n-i = c_0\}\} \text{count} := \text{count} + 1 \{\{Q''\}\} \)

Let us recall that \( Q'' \) is \( (\text{Inv}^{i+1} \wedge n-i = c_0) \).

\( Q''^{\text{count}+1} = (\text{Pre} \wedge i + 1 \in [1..n+1] \wedge \text{count} + 1 = \sum_{j=1}^{i-1} \chi(x[j] \mid k) + \chi(x[i] \mid k)) \) By

Theorem 2. it is sufficient to prove that

\( \text{Inv} \wedge i \leq n \wedge n-i = c_0 \wedge x[i] \mid k \wedge n-i = c_0 \implies Q''^{\text{count}+1}. \)
• \textit{Pre}
  \begin{itemize}
    \item \textit{Pre} in included in \textit{Inv}.
  \end{itemize}

• $i + 1 \in [1..n + 1]$
  
  Due to the invariant $i \in [1..n + 1]$ holds. This, combined with the loop condition $i \leq n$ implies
  $i + 1 \in [1..n + 1]$, $i = 1$ and $i \leq n$.

• $\text{count} + 1 = \sum_{j=1}^{i-1} \chi(x[j] \mid k)) + \chi(x[i] \mid k)$

  By the loop invariant $\text{Inv}$, $\text{count} = \sum_{j=1}^{i-1} \chi(x[j] \mid k))$. Since in this case $x[i]$ is a divisor of $k$, $\chi(x[i] \mid k) = 1$, we added 1 to both sides of the previous equation.

D. $\{\{\text{Inv} \land i \leq n \land n - i = c_0 \land x[i] \mid k \land n - i = c_0\}\} \text{skip } \{\{Q''\}\}$
  
  Let us recall that $Q''$ is $(\text{Inv}^{i+1} \land n - i = c_0)$ that is $(\text{Pre} \land i + 1 \in [1..n + 1] \land \text{count} = i - 1 \sum_{j=1}^{i-1} \chi(x[j] \mid k)) + \chi(x[i] \mid k) \land n - i = c_0)$. By Theorem 1. it is sufficient to prove that $(\text{Inv} \land i \leq n \land n - i = c_0 \land x[i] \mid k \land n - i = c_0) \implies Q''$.

• \textit{Pre}
  \begin{itemize}
    \item \textit{Pre} in included in \textit{Inv}.
  \end{itemize}

• $i + 1 \in [1..n + 1]$
  
  We prove this in the same way as we did in the previous case.

• $\text{count} = \sum_{j=1}^{i-1} \chi(x[j] \mid k)) + \chi(x[i] \mid k))$

  By the loop invariant $\text{Inv}$, $\text{count} = \sum_{j=1}^{i-1} \chi(x[j] \mid k))$. Since in this case $x[j]$ is not a divisor of $k$, $\chi(x[i] \mid k)$ evaluates to zero. The desired condition holds because both sides of the equation $\text{count} = \sum_{j=1}^{i-1} \chi(x[j] \mid k))$ in $\text{Inv}$ remained the same.

• $n - i = c_0$
  
  It is obviously true, since it is on the left side.

ii. $\{\{Q''\}\} \ i := i + 1 \ \{\{\text{Inv} \land n - i < c_0\}\}$

  $Q'' = (\text{Inv}^{i+1} \land n - i = c_0)$. It is obvious that $(\text{Inv}^{i+1} \land n - i = c_0) \implies (\text{Inv} \land n - i < c_0)^{i+1}$, therefore by Theorem 2 we get the expected correctness formula.

To prove the correctness formula $\{\{Q\}\} S \{\{R\}\}$, all the verification conditions generated by the verification rules have to be satisfied. Let us remember that the following condition was not proven:

$\text{Inv} \land i \leq n \land n - i = c_0 \subseteq D_{x[i]} \land D_{c[i]}$

We could not guarantee that both of the logical functions $x[i] \mid k$ and $x[i] \mid k$ are well-defined functions. Evaluating these functions of the program might lead to abortion. The rest of the conditions were unnecessary to prove, their proof was given for the sake of completeness.

5 \textbf{Summarization}

The main idea behind this work is to take into account abortion caused by partial functions in programs and extend verification rules to be able to ensure that such programs are total correct. To reason about correctness, we provided the formal definition of the semantics of programs under our investigation. One of the contributions of this paper is, that the semantics of program constructs are defined in such a way that they suit an existing relational model of programming. This relational model defines the program as a set of its possible executions and also provides definition for other important programming notions like problem and solution. Then, for each class of statements we provide a verification rule. The first six rules are well-known. Three rules are new, they are presented along with their proofs. The use of the rules is demonstrated by means of a verification case study.
