

Mobile Sensemaking: Exploring Proximity and Mobile Applications in the Classroom

Abstract. We propose mobile sensemaking as a collaborative mechanism to explore and understand information in highly mobile and fluid situations, where people engage in multiple parallel, rapid and ad-hoc interactions, rather than participating in large highly-structured decision processes. Mobile sensemaking is explored in the classroom context, where it has been recognized that the traditional lectures should be reconstructed as active processes centered on collaborative activities. Mobile sensemaking relies on mobile computing devices and a proximity model, both organizing collaborative activities according to the domain context and physical proximity. The paper describes in detail the proposed proximity model and the developed mobile application.

1 Introduction

Over the last recent years many systems based on mobile computing technology have been developed for supporting collaborative learning of students in the classroom. The goal of these systems has been to improve the quality, effectiveness and satisfaction of teaching, leveraging the synergies found in small collaborative groups.

With the help of appropriate mobile technology and applications, teaching and learning procedures are expected to achieve higher levels of engagement, better adjustment to individual and group learning needs, higher learning rates, and better quality of time utilization and a better flexibility of teaching for the instructors.

However, in spite of such new technology, the basic learning processes have remained largely unchanged throughout this time. Furthermore, to date, researchers have mostly focused on bringing technological innovation to the classroom, while giving relatively little attention to the more broad aspect of improving the in-class

instruction using technology in order to enrich the existing “best practices” or create new ones.

Many educators agree that the main disadvantage of the traditional classroom lecture – the one placing teachers as the major focus of attention and most critical resources – is the reduced level of interactivity between teachers and students, and among the students themselves. The limited interaction possibilities in classroom lectures originates a set of problems regarding students’ attention and motivation, reduced teachers’ awareness of the actual learning accomplishments, and lack of flexibility for handling the necessary adjustments regarding the teacher’s and students’ goals.

From a pedagogic-psychological point of view, it has been considered that learning in the classroom should be reconstructed and redefined as an active process with more involvement of the student in meaningful learning activities [4], [7]. This reconstruction would include [9]: a) promoting students’ engagement in stimulating collaborative activities; b) increasing teachers’ awareness of students’ progresses; and c) enriching the learning process with more sophisticated activities such as brainstorming, creative thinking, decision making, planning, and critical evaluation of the outcomes [14].

Interacting with their peers by being engaged in collaborative learning activities also represents an opportunity for the learner to take hand in shaping the informational, communicational and learning process, rather than remaining a passive and individual recipient. As far as the success of interactivity in the classroom is concerned, empirical results indicate that: a) lectures are not generally ineffective, but are unsuitable to a global knowledge transfer [5]; and b) the diverse learner-centered measures positively affect learning success [6].

Nevertheless, the classroom lecture remains as the most frequent teaching-learning scenario, since it has also important advantages compared to other settings. Especially important is the economic aspect regarding the teachers’ cognitive effort: only in a classroom lecture a teacher can economically deliver knowledge to a large number of students, regarding the resources involved and the time invested.

Our endeavor is to improve interactivity in the classroom while still keeping the learning process efficient in terms of resources and time. We have strong reasons to believe that mobile technology provides a technological platform capable to support the levels of interactivity required by the active learning process, and we are building software mechanisms to conserve the teachers’ effort in this process.

In this paper we show how wirelessly interconnected handheld computing devices may improve interactivity in the classroom involving university students in more sophisticated interactions than those expected in classic lectures, which in turn will foster collaborative learning. The focus of this technology is to improve sensemaking in the classroom, i.e. the students’ ability to collectively explore and understand information [16] while shifting the teacher’s role to the backstage, performing supporting activities but not coordinating the assigned tasks.

The paper is organized as follows. Section 2 describes the scenario we want to support. Section 3 defines the context and proximity concepts in this scenario. Section 4 describes our proposed proximity model for mobile sensemaking. Section 5 presents the application implementing a sensemaking activity in the classroom. Section 6 discusses this solution and concludes the paper.

2 Scenario

Our working scenario considers a common classroom situation where a teacher assigns to a large group of students the task of analyzing a large collection of papers. These papers are related in some way, but the relationships must be found out by the students through exploration and collaboration. When the task is successfully accomplished, the students should have built a coherent list of topics and identified their most significant relationships, thus defining a strategic view over the proposed research topic, without having every student to read all the papers.

The task unfolds as follows. Each student receives one or two papers from the teacher and is encouraged to find out the main topics addressed by those papers. This individual task should then contribute to the collaborative effort. Students are expected to share their findings with others, identifying common topics, establishing relationships, and avoiding misjudgments. This should unfold in a paced and informal way, avoiding losing time waiting for individual students to deliver their contributions, and in particular avoiding losing too much time discussing their divergences as a group. Instead, students are encouraged to engage in parallel negotiations with multiple parties to resolve their differences and reach consensus. Overall, the students assume the central role in the decision process, while the teacher is sent to backstage, coaching and encouraging students, assessing their accomplishments, although not coordinating the assigned task.

The fundamental aim of this task is to engage students in the sensemaking process. The sensemaking process was proposed by Weick [17] as a primary mechanism for organizations to explore and understand information. Sensemaking is an ongoing process aiming to create order and make retrospective sense about some event or collection of events. It has also been associated to preliminary decision-making activities like “understanding the situation” or “getting the picture” [6]. Sensemaking is also inherently collaborative [12], meaning that the several mechanisms defined by sensemaking (ecological change, enactment, selection, retention) rely on the capabilities of a community of people to identify cues, update and share information, identify possible actions and provide feedback on those actions.

We argue sensemaking precisely captures the decision process defined by our working scenario. When students identify new main topics, they contribute to an ecological change. These new events may be sensed by other students, who enact their responses, looking for similarities, relationships, or even misjudgments. Then, collaboratively, they may try to make sense out of such events and construct a shared and coherent view. In summary, this scenario involves students exchanging information, moving around the classroom to engage in discussions with the other parties, negotiating common interests, and ultimately making sense of information.

3 Context and Proximity in the Proposed Scenario

According to Dey [2], context is defined as any information that can be used to characterize the situation of an entity. An entity is anything relevant to the interaction between a user and an application, such as a person, a place or an object, including the

user and the application themselves. In general terms, context is typically the location, identity and state of people, groups, and computational and physical objects.

Dix et al. [3] describe four generic forms of context that influence interaction with mobile devices: infrastructure, system, domain and physical context. The infrastructure context addresses issues like the variability of services, user awareness of available services, or liveness of data. The system context is related to the management of feedback and feedthrough, support to distribution, and support to emergent behavior. The domain context considers the semantics of the application domain, e.g. the definition of the relationships between the mobile devices and their users, and how these relationships can be used to determine the application behavior. Finally, the physical context is related with the possibility that mobile devices are likely to be aware of their physical surroundings. For instance, the mobile devices may know that they are proximate to other devices (if some network connectivity is available) or in a specific classroom (e.g. if the classroom has a router installed).

Our approach explores two forms of context defined by Dix [3]: the domain and physical contexts. The domain context in our scenario is relatively complex because it combines individual and group work in a very fluid way. Students serendipitously move around the classroom forming temporary groups and holding ad-hoc interactions. The information about when groups were set up, who belonged to those groups and what interactions occurred characterizes the domain context in our scenario. This domain context should be maintained by technology to facilitate sensemaking, since it improves the retrospective understanding of the situation. The absence of domain context would represent an additional effort from the participants, who would have to search endlessly for hints about previous interactions with other students, the common topics that were found and decisions made.

We thus believe that the combination of proximity and context is a key aspect for supporting sensemaking in the classroom using handheld computing devices. We define two fundamental types of proximity contexts:

- **Environmental proximity** - The students perform their activities in the classroom. Environmental proximity contributes to define them as a group and to consolidate their expected behavior as group. Environmental proximity is thus associated to the production, sharing and sensing of topics in the classroom.
- **Close proximity** - The students engage together in very proximate face-to-face interactions, to avoid disturbing other students who may be engaged in their own interactions. Close proximity is associated to a face-to-face collaborative workspace, where two or more students share information and discuss about specific topics, their relevance and possible relationships.

Let us now discuss these matters in the physical context. According to [16], proximity is relevant when users are close to each other and, according to their location handheld computing devices may support a differentiated set of services. Physical proximity is based on the communications networks established by handheld computing devices, which are formed dynamically by juxtaposition of wireless networks created on demand. Physical proximity defines a context identifying who was physically close to each other and what information was exchanged between

them. Based on these notions, we may complete our definitions of environmental and close proximity:

- **Environmental proximity** - The students perform their activities in a confined physical space, the classroom, allowing establishing a communications network between all students' handheld devices. This allows sensing topics in the classroom.
- **Close proximity** – When the students engage together in very proximate face-to-face interactions, their handheld devices will establish a communications network. This network is distinct from the one associated to environmental proximity, and allows sharing a workspace between proximate students.

4 Proximity Model for Mobile Sensemaking

We will first consider the implications of the physical context in our model, as it has direct implications on the automatic management of contextual information. When two or more students are close to each other and wish to collaborate, the handheld computing devices will automatically activate a Close Proximity Context (CPC). The following rules apply to CPC management:

- The CPC is automatically activated when two or more handheld devices are connected together at the very proximate physical level (e.g. using IRDA).
- The CPC will be active as long as there is physical connection between at least two devices.
- The students engaged in the same CPC automatically share their workspace and the information belonging to the shared workspace is also part of the CPC.
- The CPC evolves according to the participants and shared information. This allow for several students to get anytime in and out of the discussion.
- The CPC is automatically deactivated when physical connectivity is lost.
- The deactivated CPC will remain in the handheld devices for search and navigational purposes. This functionality supports retrospective sensemaking.

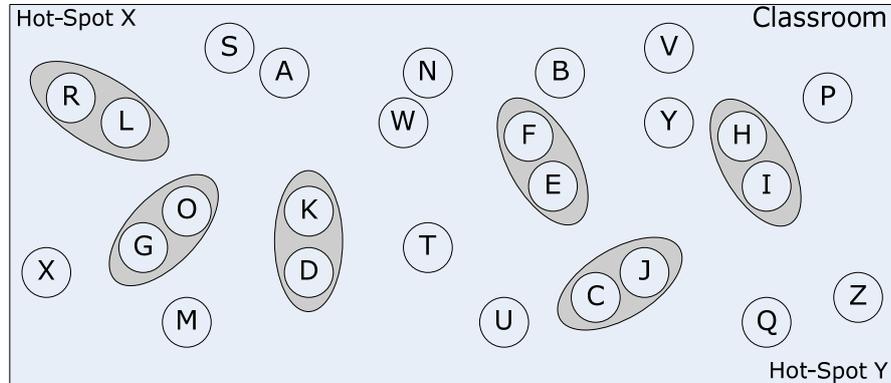

Fig. 1. The figure shows a possible configuration of the collaborative learning activity in a whole-classroom. The node labeled with T represents the teacher, the rest are students. All participants can move freely across the entire classroom. Hot-spots are known locations in the room where students can meet face-to-face in a previously agreed appointment.

Focusing on the whole classroom, we also define an Environmental Proximity Context (EPC):

- The EPC is automatically activated when several handheld devices are interconnected at the physical level (e.g. using WiFi).
- The students engaged in the EPC automatically receive indications about the topics generated by other students that may be of interest to them. This functionality uses similarity text matching.
- The students might interact with their devices to request becoming proximate to students for which some similarity has been indicated to them.

The handheld are responsible for getting the interested parties together. The proximity model for mobile sensemaking is illustrated in Figure 1 and further discussed below according to several situations.

Environmental proximity situation. The students are identified with letters from A to Z, while T represents the teacher. They all share the same classroom, and their handheld devices share the same (Wi-Fi) network. Therefore they are potentially engaged in the same EPC. However, not all students are effectively engaged in the EPC at a specific time, because they may be engaged in a close proximity situation (these are the cases of, e.g., RL, GO and KD). Within the EPC, when a student produces a topic, it is distributed to the other students' handheld devices. The devices compare their current list of topics with the distributed topic and, if there is some similarity matching, the student will be notified. Note that unrelated topics are filtered out, but they may become related later on, when students change their list of topics. If

a student wishes to discuss with the student that produced the topic, she will invoke an engagement protocol, which is described next.

EPC is useful when the student considers that the face-to-face interactions she made so far are not enough and wishes to find out possible relations between her topics and those from other students present in the same classroom. Those students may also include those with whom she already had a CPC interaction. This may occur when after a while the students may incorporate more characterization topics to the initial list proposed by the teacher, which can be used again. The cases in which such a situation may occur are the following:

- Case EPS1. Using the WiFi network, a student X (see Fig. 1.) searches for the topics other students have defined for the articles they have read. Once the student has found the topics she is interested in decides it is not necessary to try a face-to-face meeting. Nevertheless, the following situations may occur: a) student V has more detailed information about topics X is interested which V is willing to share, b) X can send information to V about the topic both are interested in, c) X and V are only interested in exchanging information about the topic but not on discussing about why they use them to characterize the article, and finally d) there is no interest in sharing information.
- Case EPS2. A student Q finds using the WiFi network that Z is willing to share information with him. In this case, it is necessary to activate the engaging process (request, accept, software defines hot-spot) in order to enable Q and Z find each other in the Hot-Spot Y. After that a CPI situation may arise.

Engagement protocol. First, the protocol requires acceptance from the invoked party. In case of acceptance, the parties must become face-to-face. Since the technology does not identify the students, the engagement protocol must utilize a scheme that does not require identification. The adopted solution involves Hot-Spots (two Hot-Spots are shown in Figure 1): the handhelds requests both parties to move towards a specific Hot-Spots (see Q and Z). Hot-Spots are a specific location in the environment (e.g. corners like Hot-Spot X and Y). The Hot-Spot selection may depend on load balancing. When students come face-to-face, we have a close proximity situation.

Close proximity situation. The students in this situation are face-to-face and share a CPC. Their handheld devices automatically establish a temporal ad-hoc network connection (IRDA). Furthermore, their devices will provide a shared workspace, where topics may be collaboratively edited and linked with other topics present in any one of the participants' handheld devices. This allows effectively exchanging and sharing topics and links across multiple devices in an epidemic way, whenever students engage in new close proximity situations. We shall consider several possible scenarios within the close proximity situation:

- Case CPS1. Students R and L engage in a social face-to-face interaction in order to share, discuss, understand and relate the topics the application context has found they share. After this interaction following situation may occur: a) that R and L could define adequate relationships between some topics specified by each

one for the articles they have read, b) that they found no relations between the common topics.

- Case CPS2. Students K and D are informed by their handhelds that they have topics in common for the articles they have read. However, they decide that a social interaction is not necessary and that is enough that: a) K sends information to D, b) D sends information to K or c) both exchange their information. This information is sent over the WiFi network and may correspond to the detail generated by each student for a certain topic and will be available only if there is mutual consent.
- Case CPS3. Students C and J are informed by their handhelds that they have not common topics on their lists so there is no need to engage in a social interaction. However, it is still possible that: a) The information J has is somehow relevant to C, who is willing to share it, b) the information C has is relevant for J, who is willing to share it, c) the information J and C have is relevant for each other and both are willing to share it, and d) the information J and C have is not relevant for the other so there is no transfer of information between them.

Disengagement protocol. The disengagement protocol occurs when one student considers that the face-to-face interaction is completed, and perhaps other students could be contacted. The disengagement occurs when the student moves away from the face-to-face interaction and the (IRDA) network connection is lost. Then, the student is again in the environmental proximity situation. As mentioned, the contextual information associated to the face-to-face interaction is preserved in the CPC.

5 Implementation of the Mobile Sensemaking Application

The application delineated in the previous sections has been implemented using a rapid development platform for mobile applications. This platform offers generic support for sketching, pen-based graphical objects manipulation, automatic ad-hoc network establishment, and object distribution and replication. The framework has been used to develop several mobile applications, such as MCSketcher [19], Nomad [20] and Participatory Simulations [21].

Also, as described in [21], the framework is able to recognize when to users engage in a face-to-face encounter, aligning their handheld devices. In this section we describe how these features were used to build the mobile sensemaking application. The application offers several User Interfaces (UIs) allowing the teacher to assess the classroom activity, and giving the students the ability to write topics associated with their assigned papers, link these topics with other topics, and engaging in collaborations with other students. Most interaction with these UIs is done with pen gestures, because it is the natural way for a user to control a handheld device.

5.1 Papers distribution.

The initial UI allows the teacher to assign papers to each student. On the left part of the screen, a list with student-icons represents all students attending to the activity. This list is populated automatically by recognizing which devices are running the application within the wireless network range. On the right part, a list with document-icons represents all papers available for reading. In order to fill up this list, the teacher may click on the “add document” icon or the “add folder icon,” both located at the beginning of the file list. Clicking opens a file browser dialog or a directory browser dialog, loading a single selected file or all documents within selected directory into the list. Figure 2 shows this UI.

Fig. 2. The teacher UI displays the list of students and available papers. On the left side the list of students is displayed (which were found by the participant discovery mechanism of the application based on multicasting messages). On the right side, the list of the papers (identified by the author’s name and publication year) is displayed. A paper is assigned to a certain student by drawing a line with the stylus from a paper’s bullet to a student’s bullet (or vice-versa).

To assign a paper to a student, the teacher must drag its document-icon over the student-icon. Dragging a student over a document-icon would also assign a paper to a student. These actions may be repeated several times, assigning multiple papers to a student and multiple students to a paper. Every time this is done, both icons will show an updated count of links over their icons: the document-icon will show how many students have been assigned to work with that paper, and the student-icon will show how many papers have been assigned to him/her (figure 2). The teacher can also randomly assign one paper to each student by clicking on the dice-icon, at the upper bound of the UI. Clicking this icon repeatedly assigns multiple papers to each student, ensuring every paper has a similar number of students assigned.

5.2 Paper reviewing and topics linking.

Once a paper has been assigned, its icon appears in the students' handheld UI. The student may double click any document-icon to trigger the document reader application and view the assigned paper. Document-icons appear in the lower part of the UI, so the rest of the UI is empty and available for writing or drawing topics related to the assigned papers. Once a topic is typed or sketched, the student may link it to one of the assigned papers by drawing a connecting line. When this happens, the system recognizes the gesture and establishes a link between the topic and the paper, represented by an arrow. A topic may be linked to several papers, and a paper may be linked to multiple topics (figure 3). Repeating the "link gesture" unlinks the topic from the paper, allowing the student to correct links created accidentally. Also, drawing a "cross gesture" can delete topics generated by the student.

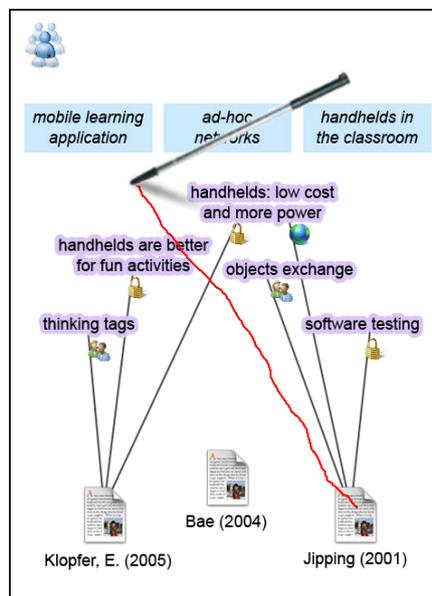

Fig. 3. Topics definition and linking UI. Using the stylus, students can link papers with related topics. Icons show the user current links' configuration, which may be public, private or available only during face-to-face encounters. Topics created by the teacher are displayed with a different border.

The teacher's UI for topics definition is normally empty. However, it allows the teacher to type or draw generic topics that may help students recognize what kind of sentences are meant to be considered as topics. When the teacher creates such topics, they appear in the students' devices along with his/her own written topics. The topics created by the teacher are displayed using different colors and borders than those created by the students. Figure 3 shows topics created by the teacher and the student.

5.3 Sharing privileges and information sharing

The objective of this application is to support a highly active pedagogic activity, allowing the students to build common knowledge in a collaborative way. Hence, participants will eventually share their ideas with others. In this application, when a student links a topic to certain paper, he or she may not be confident about their relation. Therefore, he or she may not be willing to share this idea he or she is not convinced with.

The system allows students to choose in which way they want to share generated knowledge. In this case, each link may be configured as “public”, “face-to-face only” or “private”. When a connection between a paper and a topic is configured as public, all students in the activity may access such information through the “Topic search screen” or “face-to-face discussion”, both described next. If it is configured as face-to-face only, such information will be revealed when two students engage into a face-to-face discussion, allowing the unconfident student to talk about the idea with another participant. When a topic link is configured as private it won’t be available to other students under any interaction mode until the student changes its configuration. Students may configure a link access by double clicking it on the screen using the handheld stylus. When this occurs, a small floating palette will offer the three available states that the user can click. Each link between papers and topics displays a small icon representing its sharing configuration, as shown in Figure 2. Links are created with “face-to-face only” privileges by default.

5.4 Related topic search and environmental sharing

As described in section 4, the activity encourages students to interact either in close proximity or environmentally. Students may access all knowledge generated by others configured as “public” by their authors. The “topics map” screen (figure 4) displays a diagram where every student is represented by his/her icon, including the current user centered in the middle of the screen. Each student icon is surrounded by its public topics, in a star diagram fashion.

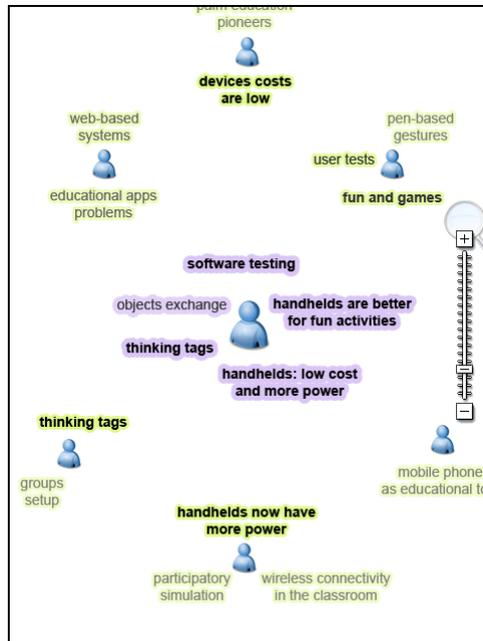

Fig. 4. The topics map UI. Other students' similar topics are displayed in bold and darker color. Double clicking another student's icon displays the interaction UI.

Smart text matching algorithms simplify the search process by organizing the topics map according to the student's interests. Topics similar to the current student's ones are displayed closer to the center, drawn in darker color if their similarity reaches a high level. The participant distribution in the screen depends on overall topics likeness: other students may be located near the center when they have a high number of coincidences between his/her topics and current student's ones.

Originally, the screen is zoomed in order to display the closest participants only. The user can drag the screen to navigate through the entire list of participant holding and dragging the stylus. Also, the user may zoom in or out clicking the magnifier icons or dragging the zoom slider at the right of the screen. Finally, the user can double click another student's icon when he/she is interested in this particular student's topics or wants to invite him/her to a face-to-face encounter. Based on these simple pen-based gestures each student may browse all public topics.

5.5 Interacting with other students

Students enter the interaction screen by double clicking another participant icon in the "topics map" screen or engaging in a proximity face-to-face interaction. The first alternative allows a user to interact in an independent and one-way only, and the second one establishes a two-way interaction. In the interaction screen, the lower region of the screen belongs to the current student, while the upper region

corresponds to the other user. The icons of papers assigned to both students are displayed beside the students' icons. These files icons may be double clicked triggering a secondary reader application, as mention before. Also, such icons are surrounded with their topics and their links to the documents. In case the interaction is triggered by a face-to-face encounter, all links configured as public and as available in face-to-face interactions are shown. When the interaction is activated from the "topics map" screen and the other student is not in front of the current user, only public topic links will be displayed.

The bottom and the top of the interaction screen display both students' topics collection. Topics from each student are horizontally sorted in order to be vertically aligned with topics from the other student based on text similitude. If their texts match exactly or above a certain peak, an automatic link between them is displayed. A student may manually link his/her topics with the other students'. To create a link between two topics he/she has to draw a line connecting their labels, in the same way as he/she linked the topics with the papers in the topics definition screen. Topic to topic links show an arrowhead according to which student created it. In case both students agree on such relation, having the two of them drawn the same link, the line will have arrowheads in both ends and get highlighted. Automatically created links always display as a two-way link. Finally, students may link their papers directly to the other users' topics. Topic-paper's links are created using the same link gesture available in the "topics definition" screen. By doing this, topic label will be relocated in the center of the screen, showing its links to papers of both students.

5.6 Engagement invitation

A student can invite another participant to a face-to-face interaction, in order to access to his/her "face-to-face only" topics and links. Invitations are generated in the interaction screen drawing a line between both students' icons. This will show a dialog which allow the students to make a *rendezvous* appointment in a certain a hot spot. The invited student will get an alert in his/her device inviting him/her to meet in the appointed location. Such alert has a "dismiss" icon, which will cancel the invitation. In this case, the first user will be notified of such response. In case the invited student accepts the proposal, both participants will meet in the assigned place and start a face-to-face interaction, as described before, entering the interaction screen.

6 Discussion & Conclusions

The use of handheld computers to support learning has attracted the attention of many authors. Among the earliest works we can cite is described in (Jippling, 2001). More works are described in [18] and [13]. In all cases, the reason for having mobile devices is to support the social face-to-face interaction and to achieve high levels of activity in the classroom, avoiding passivity of the students.

The importance and potential of context in general and awareness in particular was discovered very early in the short history of the development of collaborative mobile

applications. In [10] the author presents a works showing how context information can be used in different application areas, e.g. tourist guidance, exhibition guidance, e-mail, shopping, mobile network administration, medical care and office visitor information. In these studies, the location of the user is the main attribute used in the context-adaptation. In [1] the authors show the value of context information and social awareness for developing an application to support collaboration between experienced and novel doctors in a hospital. In [15] a mobile application which offers various services supporting office-type work which uses context-awareness, mainly information on position of the user and available services nearby. It seems there are no major contributions in the field context-aware applications for supporting collaborative learning except for those dealing with participatory simulations, like the one described in [11].

In this work, we apply the theoretical framework proposed by Dix [3] to develop a model and a whole-classroom collaborative learning application. We think this model an application can also be applied to other scenarios beside the described in section 2 where the common element is that the information about proximity between users can be used for having a context-aware application. Some of these scenarios may be conference participants using handhelds during the conference to ingress a list of topics reflecting their research interests, a small group of employees performing teamwork in an ad-hoc setting (e.g. emergency management), but they do not know in detail the responsibilities and activities of their colleagues, or any kind of activities with people doing field-work having to exchange information among each other in a reduced surrounding.
