Abstract

.

1. Extended Abstract

Even though the maturity of the Artificial Intelligence (AI) technologies is rather advanced nowadays, according to McKinsey, its adoption, deployment and application is not as wide as it could be expected. This could be attributed to many barriers including cultural ones, but above all, the lack of trust of potential users in such AI systems.

[1] studied the different factors that affect the users' trustworthiness on AI systems. Some of these factors comprise the so called Explainable Artificial Intelligence (XAI), which according to [2] refers to the "techniques that enable human users to understand, appropriately trust, and effectively manage the emerging generation of artificially intelligent partners". However, the explainability of AI systems is necessary but far from sufficient for understanding them and holding them accountable [3]. Therefore, in order to develop trustworthy AI systems, not only should they be explainable, but also accountable.

The accountability can be defined as the ability to determine whether a decision was made in accordance with procedural and substantive standards and to hold someone responsible if those standards are not met [3]. This means that with an accountable AI system, the causes that derived a given decision can be discovered, even if its underlying model's details are not fully known or must be kept secret.

Therefore, it seems reasonable to consider that the adequate representation of data, processes and workflows involved in AI systems could contribute to make them accountable. There are a variety of technologies that offer conceptual modelling capabilities to describe a domain of interest, but only ontologies combine this feature with Web compliance, formality and reasoning capabilities.

The usage of Semantic Technologies towards the achievement of Trustworthy AI has not been heavily researched in the literature, so their full potential is not exploited yet. Towards the achievement of trustworthy AI systems, this article proposes an ontology-based approach

aimed at providing Machine Learning systems with accountability. This approach consists of three phases as shown in Figure 1.

The first phase is related to the development of the predictive model and its deployment in production where it will be executed. In the second phase both the procedure followed to develop the deployed predictive model and the results produced by the predictive model are annotated with the adequate ontology terms. As for the third phase, it is responsible for managing the annotations of the previous phase and facilitating their exploitation by users.

The areas of knowledge distinguished in Machine Learning systems may be: the forecast made by the predictive model, and the procedure followed for making such a forecast. Likewise, the latter procedure-related information can be divided in the information that addresses the training data and the information concerning the predictive model itself. After considering and evaluating the suitability of different ontologies, finally, three Ontology Design Patterns (the AffectedBy ODP[1], the Execution-Executor-Procedure (EEP) ODP[2] and the Result-Context (RC) ODP[3]) and the ML-Schema[4] have been chosen for representing this knowledge.

The full potential of Semantic Technologies to fill existing gaps and unsolved challenges towards trustworthy AI systems is yet to be unlocked. This article is aimed at paving the way for future research in this direction.
