Iconic Gestures with Spatial Semantics: A Case Study

Abstract. The spontaneous gestures that accompany spoken language are particularly suited to conveying spatial information, yet their briefness, individuality, and lack of conventional linguistic structure impede their integration into NLU systems. The current work characterizes spontaneous size gestures in a manual task corpus, clarifying their form, discourse role and representation as a first step toward incorporating them into NLU systems.

Keywords: gesture, spatial language, knowledge representation.

1 Introduction

When gesture carries the primary load of communication, as in the major sign languages, it develops linguistic properties such as verb subcategorization [1] and lexicalization [2,3]. The spontaneous hand gestures that accompany speech, in contrast, do not show linguistic structure [4]. For this reason, computational research on spontaneous gesture has focused primarily on discourse functions, such as using long range video features to signal repair strategies [5] or shifts in topic [6]. Discrete-valued features extracted from gaze and body orientation have also been used for discourse functions such as signaling grounding. Much of this work emphasizes gesture production rather than recognition [7, 8, 9].

Yet the spontaneous hand gestures that accompany speech are increasingly recognized both as a cognitive aid to the gesturer, and an encoding of meaning [10, 11, 12]. Among the spontaneous gestures that accompany speech, iconic gestures are those which present “images of concrete entities and actions”[4]. Iconic gestures have in some cases (though not yet broadly) been shown to be effective in communicating spatial information between discourse participants [4, 11, 13].

The current work pursues the incorporation of spontaneous gesture into NLU systems: much groundwork must be laid. Amid the fluidity and abstractness of spontaneous gesture, we focus on concrete gestures with (relatively) straightforward spatial interpretations. We seek to answer the questions:

- What is the discourse purpose of the gestures?
- Do the gestures constitute intended communication?
- To what extent are they lexicalized?
- What are their semantics?
- How can they be related to the semantics of the co-occurring speech?
2 Corpus study

We collected a reference corpus for dialogue with intonation and gesture in a physical task context. The subjects were twelve pairs of University of Chicago undergraduate and graduate students, who were familiar with each other and had some cooking experience. They were recorded while performing a 30-45 minute cooking task (making chocolate truffles), using a single camera and lapel microphones. Some elements of the task include locating ingredients and equipment, dividing the labor, choosing flavorings, and activities such as measuring and washing up.

The resulting eight hours of videotape were examined for spatial gestures. These included pointing, displaying, miming of physical actions and manner[14], and size gestures. We selected the size gestures as a focus for possible NLU because they are the simplest and most imagistic of these groupings, and because they were relatively uniform in form.

![Image of two individuals performing a cooking task]

All of the size gestures in our corpus stemmed from the recipe step: “Take a hunk of set ganache and roll into a walnut-sized ball between your palms.” An example can be seen in Illustration 1, where subject Chris reads the recipe step aloud, envisions the ball he will roll, and enlists Jason to confirm the ball size. In total he performs the gesture for about three seconds; Jason eventually turns his head to view it for about 800ms. We will refer to this example and similar gestures as ‘the ball size gesture’.

2.1 results: ball size gesture use and discourse purpose

Of twelve pairs of subjects, two did not communicate about truffle size beyond reading the recipe. Ten discussed truffle size verbally; of these, three did not use gestures, and three used displays of ganache (dough). Four used size gestures: three ball size gestures and one caliper size gesture. Gestures were used in two main ways: to inform the partner of a desired size, or to request confirmation that a size was correct. In one case, multiple ball gestures were used to explain how an incorrect ball size leads to difficulties in baking. All gestures were used with co-occurring speech.

A ‘caliper gesture’ shows the size of a small object using parallel thumb and forefinger.

---

2.2 Intended communication – ball size and display

We classify five of the seven gestures as intended communication, on the basis that: in three cases the gesturer used motion or location to attract visual attention; in two cases the gesturer made a verbal reference to the gesture (e.g. “like this?”), and in one case both were used. For the seventh gesture (the incorrect ball size explanation) we have no evidence that the gesture per se was intended communicatively. A further analysis of gaze and uptake in these cases is in progress. Although this is a very small sample, most of these gestures showed evidence of communicative intent.

2.3 Form constraints on the ball size gesture

We initially suspected that the ball size gesture was strongly lexicalized in comparison with spontaneous gesture generally. In all cases the thumb and forefinger circle to touch each other and embrace a notional ball, and are displayed as the focal side of the gesture. However, there is notable variation in other parameters. Either hand could be used, as in ASL. The position of the other three fingers is not conventionalized (where it might or might not be constrained in a sign language.) The location of the gesture relative to the gesturer is not as conventionalized as it would be in ASL. In the table, we refer to the gesturer as G and the observer as O.

The third column, the explanation of how two balls may melt into each other while baking, is more typical of spontaneous gesture in showing dynamic configurational elements with extended duration. The ball size gesture is not as conventionalized as an ASL gesture – nor can we say what lexicon it would belong to. More work is needed on this point. The ball size gesture contrasts with the caliper gesture in form.

3 Representing Size

Finally we consider semantic representation. A size is a property of a physical object, generally represented as a value on a scale, where a scale is a partial ordering on a set of elements. The majority of verbal size descriptions followed the recipe text: ‘the
size of a” small object, or simply mentioned a small object: walnut, half a walnut, meatball. The comparative “...smaller”, and (negated) intensifier “don't make it too big!” also occurred. The scale in this case seems to be based on the generics (types) of ball shaped food items, and the asserted relation is purely qualitative. Qualitative representations [15, 16] may prove extensible. Gesture's spatial medium, by contrast, is continuous rather than discrete; the underlying scale is tied to the visual or perhaps kinesic system. What representation could plausibly be generated by the visual system? Our preliminary work investigates low level features in the spirit of [17, 18].
